

Hash Tables

CS 5301
Fall 2013

Jill Seaman

Main + Savitch: chapter 12.2-3
Weiss: chapter 20

1

What are hash tables?

- A Hash Table is used to implement a **set** (or a **search table**), providing basic operations in constant time:
 - insert
 - remove (optional)
 - find
 - makeEmpty (need not be constant time)
- It uses a function that maps an object in the set (a key) to its location in the table.
- The function is called a **hash function**.

2

Using a hash function

	values
[0]	Empty
[1]	4501
[2]	Empty
[3]	7803
[4]	Empty
.	.
.	.
.	.
[97]	Empty
[98]	2298
[99]	3699

HandyParts company makes no more than 100 different parts. But the parts all have four digit numbers.

This hash function can be used to store and retrieve parts in an array.

$$\text{Hash}(\text{partNum}) = \text{partNum} \% 100$$

41

Placing elements in the array

	values
[0]	Empty
[1]	4501
[2]	Empty
[3]	7803
[4]	Empty
.	.
.	.
.	.
[97]	Empty
[98]	2298
[99]	3699

Use the hash function

$$\text{Hash}(\text{partNum}) = \text{partNum} \% 100$$

to place the element with part number 5502 in the array.

42

Placing elements in the array

	values
[0]	Empty
[1]	4501
[2]	5502
[3]	7803
[4]	Empty
.	.
.	.
[97]	Empty
[98]	2298
[99]	3699

Next place part number 6702 in the array.

$$\text{Hash}(\text{partNum}) = \text{partNum} \% 100$$

$$6702 \% 100 = 2$$

But values[2] is already occupied.

COLLISION OCCURS

43

How to resolve the collision?

	values
[0]	Empty
[1]	4501
[2]	5502
[3]	7803
[4]	Empty
.	.
.	.
[97]	Empty
[98]	2298
[99]	3699

One way is by linear probing. This uses the following function

$$(\text{HashValue} + 1) \% 100$$

repeatedly until an empty location is found for part number 6702.

44

Resolving the collision

	values
[0]	Empty
[1]	4501
[2]	5502
[3]	7803
[4]	Empty
.	.
.	.
[97]	Empty
[98]	2298
[99]	3699

Still looking for a place for 6702 using the function

$$(\text{HashValue} + 1) \% 100$$

45

Collision resolved

	values
[0]	Empty
[1]	4501
[2]	5502
[3]	7803
[4]	Empty
.	.
.	.
[97]	Empty
[98]	2298
[99]	3699

Part 6702 can be placed at the location with index 4.

46

Collision resolved

	values
[0]	Empty
[1]	4501
[2]	5502
[3]	7803
[4]	6702
.	.
.	.
.	.
[97]	Empty
[98]	2298
[99]	3699

Part 6702 is placed at the location with index 4.

Where would the part with number 4598 be placed using linear probing?

47

Hashing concepts

- **Hash Table:** where objects are stored by according to their key (usually an array)
 - **key:** attribute of an object used for searching/ sorting
 - number of valid keys usually greater than number of slots in the table
 - number of keys in use usually much smaller than table size.
- **Hash function:** maps keys to a Table index
- **Collision:** when two separate keys hash to the same location

10

Hashing concepts

- **Collision resolution:** method for finding an open spot in the table for a key that has collided with another key already in the table.
- **Load Factor:** the fraction of the hash table that is full
 - may be given as a percentage: 50%
 - may be given as a fraction in the range from 0 to 1, as in: .5

11

Hash Function

- **Goals:**
 - computation should be fast
 - should minimize collisions (good distribution)
- **Some issues:**
 - should depend on ALL of the key (not just the last 2 digits or first 3 characters, which may not themselves be well distributed)

12

Hash Function

- Final step of hash function is usually:
 - temp % size
 - temp is some intermediate result
 - size is the hash table size
 - ensures the value is a valid location in the table
- Picking a value for size:
 - Bad choices:
 - ◊ a power of 2: then the result is only the lowest order bits of temp (not based on whole key)
 - ◊ a power of 10: result is only lowest order digits of decimal number
 - Good choices: prime numbers

13

Collision Resolution: Linear Probing

- Insert: When there is a collision, search sequentially for the next available slot
- Find: if the key is not at the hashed location, keep searching sequentially for it.
 - if it reaches an empty slot, the key is not found
- Problem: if the the table is somewhat full, it may take a long time to find the open slot.
- Problem: Removing an element in the middle of a chain

14

Linear Probing: Example

- Insert: 89, 18, 49, 58, 69, hash(k) = k mod 10

Probing function (attempt i): $h_i(K) = (\text{hash}(K) + i) \% \text{tablesize}$

	Empty Table	After 89	After 18	After 49	After 58	After 69
0				49	49	49
1					58	58
2						69
3						
4						
5						
6						
7						
8			18	18	18	18
9		89	89	89	89	89

49 is in 0 because
9 was full

58 is in 1 because
8, 9, 0 were full

69 is in 1 because
9, 0 were full

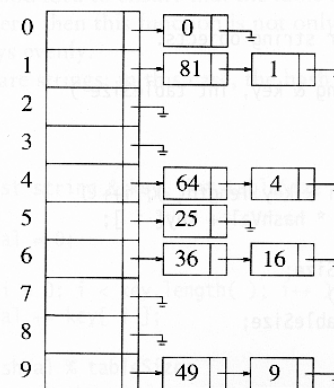

15

Collision Resolution: Separate chaining

- Use an array of linked lists for the hash table
- Each linked list contains all objects that hashed to that location

- no collisions

Hash function is still:
 $h(K) = k \% 10$

16

Separate Chaining

- To insert a an object:
 - compute hash(k)
 - insert at front of list at that location (if empty, make first node)
- To find an object:
 - compute hash(k)
 - search the linked list there for the key of the object
- To delete an object:
 - compute hash(k)
 - search the linked list there for the key of the object
 - if found, remove it
