# C++ Programming on Linux Multi-file development

CS 2308 Spring 2014

Jill Seaman

## Programs with Multiple Files

- How the code is usually split up
  - \* Put main in its own file, with helper functions
    - acts like a driver
  - \* Put each class declaration in a separate \*.h file (called a header file)
  - \* Put the implementation of each class (the member function definitions) in its own \*.cpp file
  - \* Each \*.cpp file (including the driver) must #include the header file (\*.h) of each class that it uses or implements.

2

## Time class, separate files

#### Time.h

#### Driver.cpp #include <string> //Example using Time class #include<iostream> using namespace std; #include "Time.h" // models a 12 hour clock using namespace std; class Time { int main() { private: Time t; int hour: t.setHour(12); int minute; t.setMinute(58); void addHour(); cout << t.display() <<endl;</pre> t.addMinute(); public: cout << t.display() << endl;</pre> t.addMinute(); void setHour(int); cout << t.display() << endl;</pre> void setMinute(int); return 0; int getHour() const; int getMinute() const; string display() const; void addMinute();

# Time class, separate files

#### Time.cpp

```
void Time::addHour() {
#include <iomanip>
#include <sstream>
                                   if (hour == 12)
#include "Time.h"
                                      hour = 1:
using namespace std;
                                   else
                                       hour++:
void Time::setHour(int hr) {
 hour = hr;
                                 void Time::addMinute() {
                                   if (minute == 59) {
                                      minute = 0;
void Time::setMinute(int min) {
                                      addHour();
 minute = min;
                                   } else
                                      minute++:
int Time::getHour() const {
                                 string Time::display() const {
 return hour;
                                    ostringstream sout;
                                    sout.fill('0');
                                    sout << hour << ":"
int Time::getMinute() const {
                                         << setw(2) << minute;
 return minute;
                                    return sout.str();
```

# How to compile a multiple file program

• From the command line (either order):

```
[...]$g++ Time.cpp Driver.cpp
```

- The header file should not be listed.
   (it only needs to be #included in \*.cpp files)
- \* one (and only one) file must have the main function

12:58 12:59 1:00

5

## **Separate Compilation**

- If we make a change to Driver.cpp, we have to recompile it
  - but we would rather not have to recompile Time.cpp as well.
- We can compile one file at a time, and link the results together later to make the executable.
- Compiling without linking (use -c option):

```
[...]$g++ -c Time.cpp
[...]$g++ -c Driver.cpp
```

\* -c option produces <u>object files</u>, with a .o extension (Time.o, Driver.o)

# **Separate Compilation**

• The .o files must be linked together to produce the executable file (a.out):

```
[...]$ g++ Time.o Driver.o Note there is no option used here
```

 Now if we change only Time.cpp, we can recompile just Time.cpp, and link the new .o file to the original Driver.o file:

#### Make

- Make is a utility that manages (separate) compilation of large groups of source files.
- After the first time a project is compiled, make re-compiles only the changed files (and the files depending on the changed files).
- These dependencies are defined by rules contained in a makefile.
- The rules are defined and managed by humans (programmers).

8

#### Make

Rule format:

```
target: [prerequisite files]
<tab>[command to execute]
```

- target is a filename (or an action/goal name)
- In order to produce the target file, the prerequisite files must exist and be up to date (if not, make finds a rule to produce them).
- An example rule:

```
Time.o: Time.cpp Time.h
   g++ -c Time.cpp
```

If Time.cpp or Time.h has changed, reproduce Time.o using this command

0

#### Make

- executing make from the linux/unix prompt with no arguments executes first rule in the makefile.
  - \* This may trigger execution of other rules.

```
[...]$ make
```

executing the make command followed by a target executes the rule for that target.

```
[...]$ make Time.o
```

10

#### Makefile

• makefile (a text file named "makefile"):

```
#makefile

timeTest: Driver.o Time.o
   g++ Driver.o Time.o -o timeTest

Driver.o: Driver.cpp Time.h
   g++ -c Driver.cpp

Time.o: Time.cpp Time.h
   g++ -c Time.cpp
```

You can use nano or (maybe) notepad to create this file

Do **not** copy/paste this to your makefile,

Don't forget the tabs

 Note: "timeTest" is the name of the executable file in this example (not a.out).

# Compile class + driver using make

```
• Make: [...]$ make
g++ -c Driver.cpp
g++ -c Time.cpp
g++ Driver.o Time.o -o timeTest
```

```
Execute: [...]$ ./timeTest
12:58
12:59
1:00
```

Modify Driver.cpp, make again:

```
[...]$ make
g++ -c Driver.cpp
g++ Driver.o Time.o -o timeTest
```
