

Implementation

Tsui: Chapter 9
Sommerville: Sections 7.3.2+7.4

1

Implementation

Outline:

- I. Characteristics of a Good Implementation
- II. Programming practices:
 1. Programming Style and Coding Guidelines
 2. Comments
 3. Debugging
 4. Performance Optimization
- III. Implementation Issues
 1. Configuration Management
 2. Open Source Development

2

Characteristics of a good Implementation

- **Readability:** code can be easily read and understood by other programmers.
- **Maintainability:** code can be easily modified and maintained.
- **Performance:** code performs as fast as possible.
- **Traceability:** all elements of code should correspond to a design element
- **Correctness:** it should perform as intended, with respect to requirements and detailed design.
- **Completeness:** it meets **all** system requirements.

3

Tradeoffs and interactions of characteristics

- Readability usually helps maintainability.
- Readability and maintainability usually help achieve correctness
 - how? debugging is much easier.
- Performance optimizations often reduce readability and maintainability.

4

How to achieve the desired implementation characteristics

- **Readability and maintainability**
 - Programming style and coding guidelines
 - Using comments well
 - Refactoring
- **Correctness**
 - Testing and debugging
- **Performance**
 - Optimization

5

Programming style and coding guidelines

- **Naming**
 - Good names contribute significantly to improving readability.
 - Well chosen names convey the intent of the element
 - Poorly chosen names are misleading and confusing
 - ❖ often indicate programmer does not understand the code or that the element is poorly designed.
 - File name should correspond to elements it contains
- **Indentation**
 - Use indentation to reflect the structure of the code
- **Function size**
 - Large functions are more error prone (and less cohesive)

6

Comments

- **Should be used to enhance understanding of code**
 - Good example: explaining the interface of a class or function
- **Problems:**
 - When they distract from the code (clutter)
 - When they are wrong or misleading
- **Examples of poor uses of comments**
 - Commenting out entire sections of code
 - ❖ may not be clear it's commented out
 - ❖ why is it there?
 - Comments that explain the code
 - ❖ usually a cover up for poorly written code
 - Commenting out output statements used for debugging
 - Indicating when code was changed by who for what reason
 - ❖ This info can be found using version control system

7

Debugging

- **Fixing errors in the code**
 - especially run-time/logic errors
- **Process:**
 1. **Reproduce the error**
 - Write a test case that demonstrates the error
 2. **Find the section of code that leads to the error**
 - See next slide
 3. **Correct the code**
 - Don't do this first! Don't guess!
 4. **Verify the fix**
 - Re-run the test case and make sure you get no error

8

Debugging

Debugging methods:

- Temporary output statements inserted into code:
 - view values of variables
 - analyze control flow
- Interactive debuggers
 - Tool used to view variables, step through the code, insert breakpoints
 - Sometimes have a steep learning curve
- Profilers
 - Tool that gives statistics about code, or memory while code is executing, or other metrics

9

Performance Optimization

- Improving performance requires changes to code that often make it less readable and maintainable.
- Many programmers worry about performance too early.
 - Instead you should write readable code first and then add performance improvements later, as needed.
- How to optimize:
 - Use a profiler to determine how much time is spent on each part of the program
 - first get a baseline, find the problematic areas
 - after code is modified, run profiler again and compare to baseline.

10

Implementation issues

- Aspects of implementation that are important to software engineering but not covered in programming textbooks
 - **Configuration management:** managing the different versions of each software component (the source code).
 - **Open source development:** when the source code of the system is publicly available.

11

Configuration management

- Potential problems of team development
 - Interference: Changes made by one programmer could overwrite a change previously made by another.
 - Redo good work: Programmers accessing out-of-date versions could re-implement work already done.
 - Can't undo bad work: Figuring out how to undo problems introduced into a previously functioning system.
- Configuration management: Process of managing a changing software system, so all developers can
 - access code and documentation in a controlled way
 - find out what changes have been made
 - compile and link components to create the system.

12

Fundamental configuration management activities

- Version management
 - track different versions of the files in the program
 - coordinate work of multiple developers.
- System integration
 - define which versions of each component and/or file are used for a given version of the overall system.
 - then builds system automatically
- Problem tracking
 - allows users to report and track bugs.
 - allows developers to track progress on fixing bugs.

13

Configuration management tools

- Integrated tools: all three components in one
 - tools share same interface, can share information
 - ClearCase
- Version management
 - CMVC, CVS, subversion, git, mercurial.
- System integration (build tools)
 - make (unix), Apache Ant, or built into IDE
- Problem tracking
 - bugzilla
 - any database

14

Open source development

- The source code of the system is publicly available
- Volunteers are invited to participate in the development process (may be users).
- Some open source projects:
 - Linux, Apache web server, Java
 - Eclipse, FireFox, Thunderbird, Open Office
- Issues for the developer:
 - Should an open source approach be used for the software's development?
 - Should the system being developed (re)use open source software components?

15

Open source development

- How to make money developing open source products?
 - Development is cheaper: volunteer labor.
 - The company can sell support services
 - Software must have wide appeal
- Re-using open source software in software products:
 - These components are generally free.
 - These components are generally well-tested.
 - There may be licensing issues. . .

16

Open source licenses

- **GNU General Public License (GPL).**
 - reciprocal
 - if you re-use this open source software in your software then you must make your software open source.
- **GNU Lesser General Public License (LGPL)**
 - you can write components that link to open source code without having to publish the source of these components.
- **Berkley Standard Distribution (BSD) License.**
 - non-reciprocal
 - not obliged to re-publish any changes or modifications made to open source code.
 - you may include the code in proprietary systems that are sold.
